### ■ Inferring shape from X

*Mathematica* demos.

## ■ Focus on computation of local, view-dependent shape from shading

### Perception of "Shape from X"

#### How can we define shape more precisely?

One mathematical definition: "Geometrical properties that are invariant over translation and scale".

A computational vision definition: "Whatever is left over after discounting material, illumination and viewpoint variations in the images of an object"

We will take a more general view here:

"geometrical relationships within a surface that are useful for visual functions". More precise definitions depend on the function.

Later we will return to the "discounting" issues.

We've seen that there is a variety of cues to shape. In natural images, these cues typically co-vary. Human vision can infer shape from any of them or in combination, hence "shape from X".

Later on we will talk about cue integration. In a psychophysics lab, they can be manipulated independently.

Last time we had an overview of cues to distance and to shape.

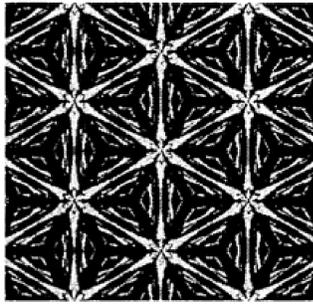

Let's look more closely at several categories of shape cues, including some for the last lecture.

#### Texture

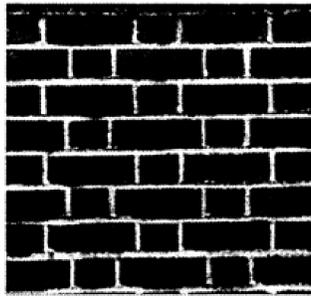

The term "texture" can be used in two different contexts. An object's texture can be informative as to its material. But texture can also be informative as to an object's shape.

(Later on we will talk in more detail about how to model and infer surface material properties which may be characterized by texture patterns.)

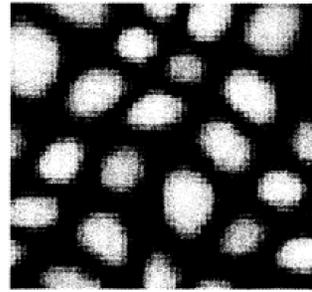

Texture by definition has a degree of regularity represented by a pattern that gets repeated. Texture can be highly regular, or only regular in a statistical sense. Textures can be precisely defined in terms of symmetries. In particular, translational symmetry says that a pattern remains unchanged if shifted by a discrete amount. For a stochastic or statistical texture, there is a statistic or collection of statistics (e.g. intensity variance, or local correlation) that is unchanged with spatial translation. Textures are sometimes described as spatially "homogeneous" with respect to some statistical measure. And sometimes the adjective "uniform" is added to make sure that one isn't referring to texture that is deviating from homogeneity, i.e. becoming a spatial "flow".

Regular

Near-regular

Irregular

From: <http://repository.cmu.edu/robotics/687>, Deformable texture : the irregular-regular-irregular cycle. Yanxi Liu and Wen-Chieh Lin.

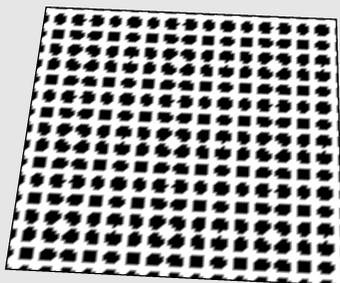

Suppose a surface has a deterministic regular homogeneous pattern of “texture elements”, where each texture element is the same 3D size, and they are distributed homogeneously. The general idea behind “shape from texture” is to assume that this underlying uniform texture that has gotten deformed by a change in the viewpoint relative to the surface patch being viewed. Let’s first look at the simplest case where we have a planar surface and we want to estimate the orientation of the surface relative to the viewpoint. When we think about “shape”, a small planar surface can be considered a local approximation to a curved surface, and then shape from texture amounts to computing surface normal vectors over each patch. But the same texture cues can also be used to estimate the orientation of a large flat surface (such as a table top).

### ■ Texture and slant/tilt

Define a function to place circular disks on a regular grid

```
checker[x_,y_,space_,radius_]:= If[(Mod[x,space]^2+Mod[y,space]^2<radius^2) || (M
pic = Table[{checker[x, y, 32, 12]}, {x, 1, 512}, {y, 1, 512}];
```

```
ListPlot3D[Table[1, {x, -5, 5, .1}, {y, -5, 5, .1}], Mesh -> None,
VertexColors -> {pic[[5 ;; -5 ;; 5, 5 ;; -5 ;; 5]]}, Lighting -> "Neutral"]
```

## How important is the contour information? Judge the local orientation through an aperture (use a straw or a rolled-up piece of paper)

The generative assumptions above lead to regularities in the image that can be used to estimate surface slant--if the spatial scale of the texture is small in comparison to the surface curvature, so that the surface can be approximated locally by a plane.

Then, cues to surface slant:

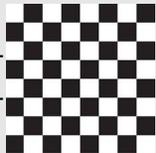

- 1) spatial gradient of the density of texture elements ("tokens"): the image token density increases with distance;
- 2) an individual element (such as a circular disk) gets smaller with distance, and its image height to width ratio gets smaller ("compressed") with increasing slant;
- 3) the ratio of the back width to the front width of an individual element gets smaller with slant (imagine a small square, linear perspective on small scale) .

(See Knill).

Tilt is the direction that the surface slants away most rapidly. Here the density and sizes of the elements change the most rapidly.

### ■ Texture and shape

```
Plot3D[Sin[0 + Sin[y / 2]], {x, -8, 8}, {y, -8, 8},
```

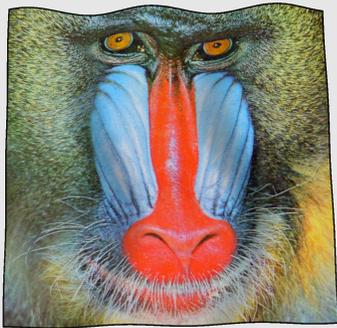

```
PlotStyle -> Texture[, BoxRatios -> {1, 1, 0.08},
```

```
Lighting -> "Neutral"]
```

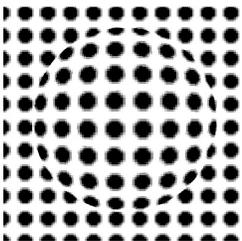

Try mapping an inhomogeneous pattern. In this demo, you can experience the perceptual tension between different sources of shape information. There are texture changes due to the 3D surface onto which the Mandrill has gotten mapped, texture and material changes due to the original actual shape of the Mandrill's head. And as you rotate, you experience motion flow cues from the 3D surface.

```
pic = Reverse[ExampleData[{"TestImage", "Mandrill"}, "Data"] / 255.];
Plot3D[Sin[x + Sin[y / 2]], {x, -8, 8}, {y, -8, 8}, PlotStyle -> Texture[pic],
  BoxRatios -> {1, 1, 0.08}, Lighting -> "Neutral"]
```

**Shape and texture: Adapt the above function to map a texture onto a smooth shape**

**Project idea: Map a small single textural element (e.g. a disk) onto an "invisible" bump. Allow the user to move the element around. Does your perceptual system infer the underlying shape?**

## Stereo disparity

### ■ Random dot stereograms

A simple planar surface in depth.

<http://demonstrations.wolfram.com/FloatingDiskStereogram/>

Cross your eyes so that you see three dots (rather than two) at the bottom. The above surface should appear like the one below, but viewed from above.

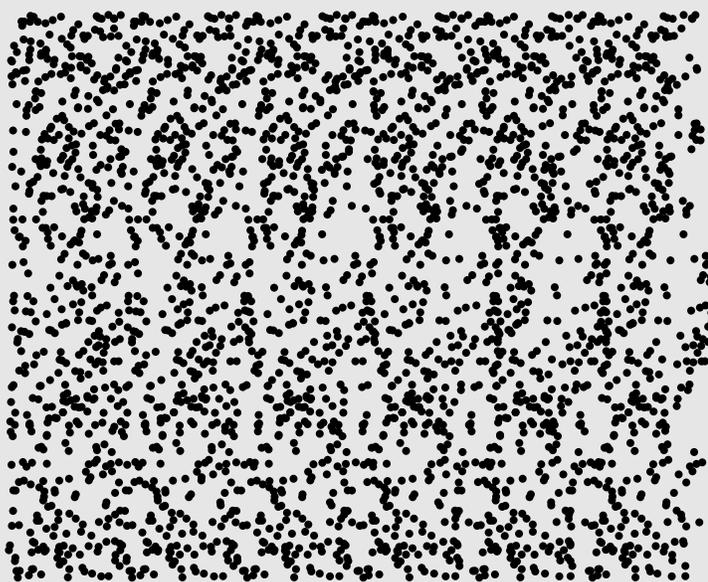

But smooth shape can also be conveyed through disparity -- "shape from stereo".

### ■ Random dot stereograms, "Magic eye" style

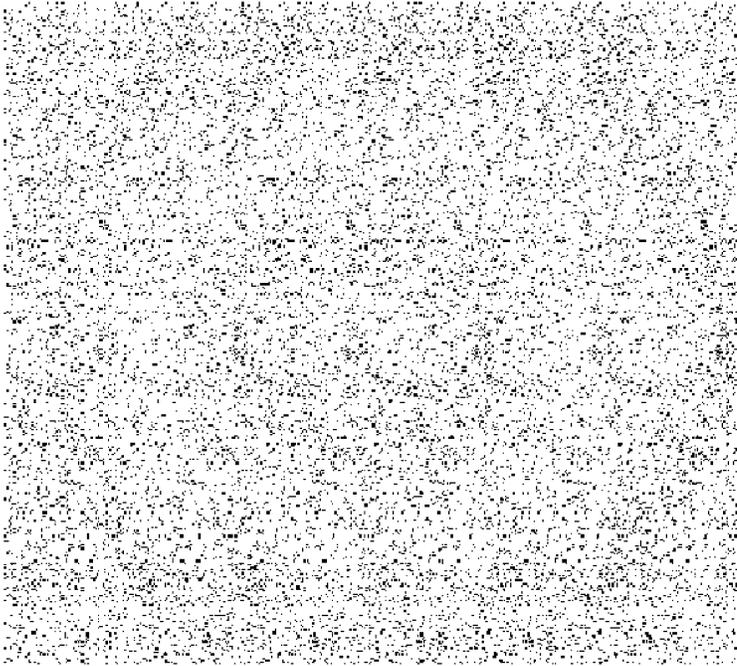

```
(*Copyright (c) Dror Bar-Natan 1994*)
(*Random Dot Stereograms in The Mathematica Journal 1-
  3 (1991) 69-75).*)

f[x_, y_] := Sin[20 (x^2 + y^2)] / (1 + 5 (x^2 + y^2))
(*the function drawn*)

Show[
  Graphics[Table[(*loop 500 times*)
    x = Random[Real, {-1, -0.6}];
    (*generate a random number between -1 and -0.6*)
    y = Random[Real, {-1, 1}];
    (*generate a random number between -1 and 1*)
    Table[(*loop 6 times*) x0 = x; x = x + 0.4 + f[x, y] / 15;
      (*compute coordinates of next pixel*) Point[{x0, y}],
      (*put a point*) {6}], (*end inner loop*)
    {500}]]]
(*end outer loop*)
```

Here's one at a higher dot density:

See: Christopher Tyler. The wiki page provides nice summary: <http://en.wikipedia.org/wiki/Autostereogram>.

---

### **Project idea: Does human vision show orientation-selective adaptation to stereoscopically defined shape?**

---

#### **■ Stereo + shading + surface contours**

In general, there are multiple cues to shape.

In[59]:=

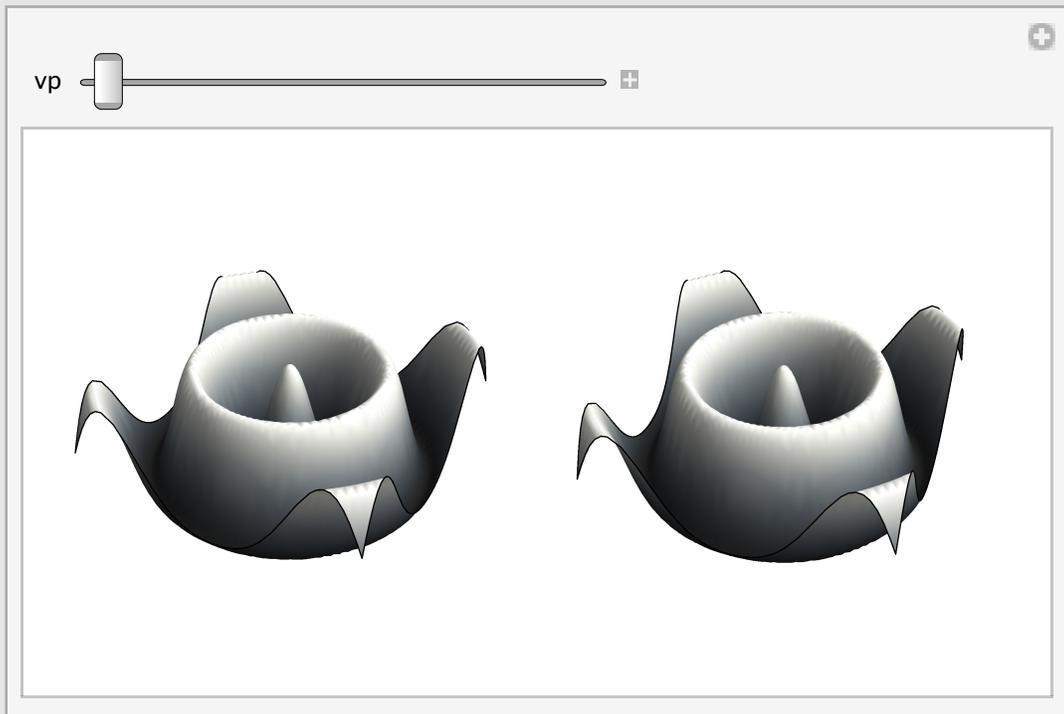

```
pL=Plot3D[Cos[Sqrt[x^2+y^2]], {x,-10,10}, {y, -10, 10},  
  AspectRatio -> Automatic, PlotPoints-> {25,25}, ViewPoint->{1.3,-2.4,2.}];
```

In[60]:=

```
Manipulate[
  pR = Plot3D[Cos[Sqrt[x^2 + y^2]], {x, -10, 10}, {y, -10, 10},
    AspectRatio -> Automatic, PlotPoints -> {25, 25},
    ViewPoint -> {vp, -2.4, 2.}];

  Show[GraphicsRow[{pL, pR}], {{vp, .8}, 0.8, 1.5}]
```

Out[60]=

## Motion

We'll look at structure & shape from motion in detail later. With some care, one can put up an animation in which any single frame shows no apparent structure, but when moving, the shape becomes clear. E.g. rotating "glass" cylinder with dots on it. Or, "biological motion".

random.mov

cube.mov

## Contours

### ■ Surface contour (markings)

```
Plot[{Sin[x], Sin[x]+1, Sin[x]+2, Sin[x]+3, Sin[x]+4, Sin[x]+5}, {x, 0, 10}, Axes->Fal
```

### ■ Shape from moving contours

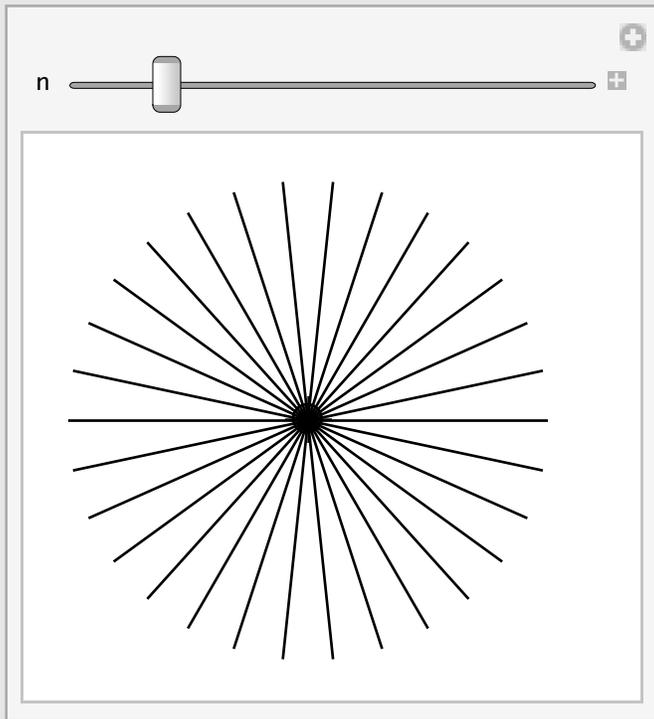

Here's an example taken from the *Mathematica* documentation. Apparent 3D shape emerges only with movement.

```
nsize = 128;
subsize = 32;
noise = Table[RandomReal[], {nsize}, {nsize}];
subnoise = Table[RandomReal[], {subsize}, {subsize}];
gn = ArrayPlot[noise, PlotRange -> {0, 1}, PixelConstrained -> {1, 1}];
gsn = ArrayPlot[subnoise, PlotRange -> {0, 1}, PixelConstrained -> {1, 1}];
```

In the demonstration below, use the computer mouse to drag the point where the lines converge.

**Manipulate[**

```
Graphics[Line[Table[{{Cos[t], Sin[t]}, pt}, {t, 2. Pi / n, 2. Pi, 2. Pi / n}]]],  
PlotRange -> 1, ImageSize -> Small], {{n, 30}, 1, 200, 1},  
{{pt, {0, 0}}, Locator}]
```

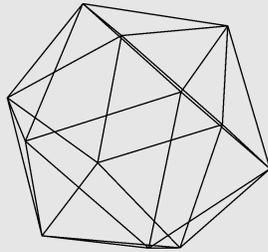

■ **Surface contours (creases or orientation discontinuities)**

The lines mark surface orientation discontinuities.

<< **PolyhedronOperations`**

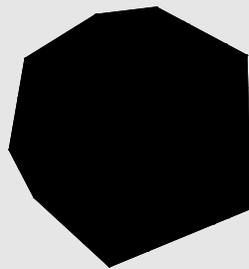

```
Graphics3D[{Yellow, Opacity[.0],
  PolyhedronData["GreatDodecahedron", "Faces"]}, Boxed → False,
  ImageSize → Small]
```

### ■ Bounding contours, (depth discontinuities), e.g. silhouette

Orientation discontinuities can coincide with depth discontinuities.

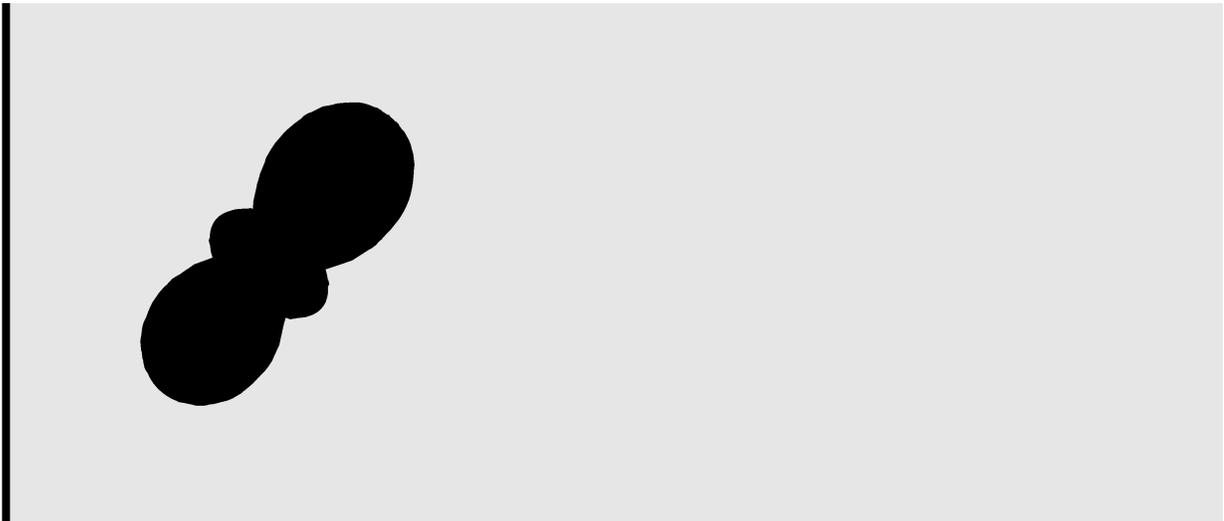

```
Graphics3D[
  {Black, Opacity[1], PolyhedronData["GreatDodecahedron", "Faces"]},
  Boxed → False, Lighting → {"Ambient", Orange}, ImageSize → Small]
```

### ■ ...and smooth occluding contours

In this smooth shape, orientation of a unit normal vector changes smoothly at the depth discontinuities of the boundary.

```
SphericalPlot3D[1 + 2 Cos[2  $\theta$ ], { $\theta$ , 0, Pi}, { $\phi$ , 0, 2 Pi}, Lighting  $\rightarrow$  None,  
Boxed  $\rightarrow$  False, Axes  $\rightarrow$  False, AspectRatio  $\rightarrow$  1, ImageSize  $\rightarrow$  Small]
```

For a concrete example of computing shape, let's focus on the problem of shape from shading...

---

## Computing shape from shading

### Introduction

The ambiguity of shading has had a newsworthy impact for well over a century, beginning with the "canals of Mars". Beginning in 1877, these "canals" attracted world-wide attention when the Italian astronomer, Giovanni Virginio Schiaparelli reported about a hundred of them. The American astronomer Percival Lowell thought the markings were vegetation, several kilometres wide, bordering irrigation canals dug by intelligent life to carry water from the poles. However, most astronomers couldn't see the canals. Photography through the Earth's atmosphere offered no solution because the lines were near the limit of resolution of the human eye and the physical optics of the time. The controversy was firmly settled in 1969 when photographs were taken from several hundred kilometres above the surface of Mars by the Mariner 6 and 7 spacecraft. These showed many craters and other formations but no canals.

However, the phenomenon of seeing intriguing shapes from shading hadn't gone away even in the late 20th century. With the Viking orbiter of 1976, NASA photographs produced a number of interesting pictures from Mars:

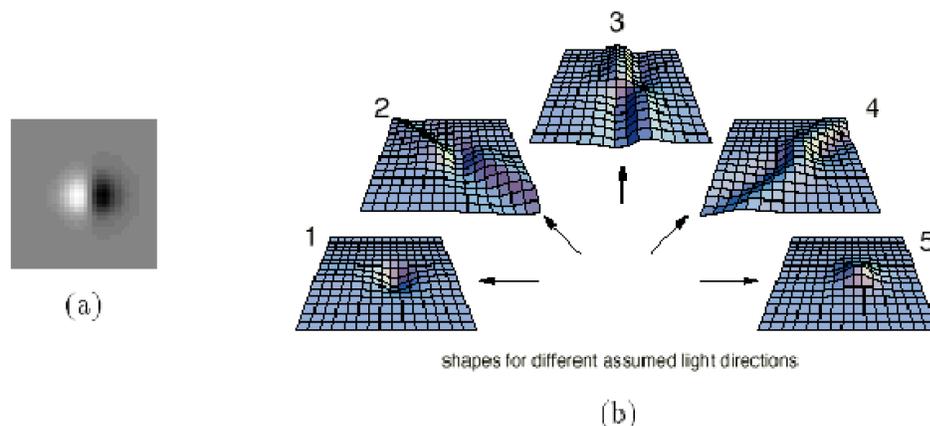

Are these shapes we see really there? If not, why do we see the particular shapes that we do?

## The ambiguities

Shape from shading is fascinating from a computational perspective--there is considerable local ambiguity, yet human vision is so sure of what it sees. To appreciate vision's solution, let's take a closer look at the ambiguities.

The following figure from William Freeman at MIT illustrates the light-direction/shape ambiguity problem of shape from shading:

**Figure 6:** (a) Perceptually, this image has two possible interpretations. It could be a bump, lit from the left, or a dimple, lit from the right. (b) Mathematically, there are many possible interpretations. For a sufficiently shallow incident light angle, if we assume different light directions, we find different shapes, each of which could account for the observed image.

## Classic regularization approach to shape from shading (Ikeuchi and Horn, 1981)

See chapter 4 in Horn's book "Robot Vision": [http://people.csail.mit.edu/bkph/articles/Shape\\_from\\_Shading.pdf](http://people.csail.mit.edu/bkph/articles/Shape_from_Shading.pdf)

Shape from shading can be treated as an inverse problem. Earlier in the course, we saw that inverse problems can be formalized in terms of Bayesian estimation. Recall that for scene-from-image problems, we start off with the generative model, and then seek an inverse solution.

Let's look at a classical solution to shape from shading due to Ikeuchi and Horn. Although it was not originally formulated as a Bayesian inference problem, it is essentially equivalent to MAP estimation.

Write down the Lambertian generative model for image luminance  $L$  in terms of geometrical gradient space parameters  $p$ ,  $q$ :

$$L_R = re \hat{N} \cdot \hat{E}$$

where  $r$  is the reflectance, and  $e$  the strength of illumination.  $N$  and  $E$  are unit vectors, as in the last lecture.  $E$  is a point light source (we'll assume  $e=1$ ), and  $E$  and  $N$ 's directions can be expressed in gradient space:

$$\hat{E} = \frac{(p_e, q_e, -1)}{\sqrt{p_e^2 + q_e^2 + 1}}$$

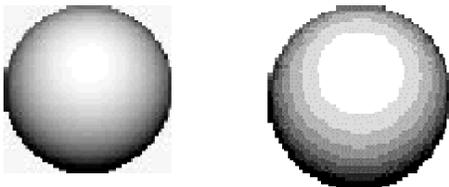

$$\hat{N} = \frac{(p, q, -1)}{\sqrt{p^2 + q^2 + 1}}$$

Taking the dot product, we have:

$$L_R(p, q) = \frac{r(pp_e + qq_e + 1)}{\sqrt{(p^2 + q^2 + 1)(p_e^2 + q_e^2 + 1)}}$$

Our data is  $L(x,y)$ . We require that our model satisfy the data, i.e. that  $L(x,y) = L_R(p,q)$ . One problem is that we do not know the reflectance  $r$  or the light source direction  $(p_e, q_e)$ . (Note that in general,  $r$  is not going to be a constant, but rather some pattern of pigmentation,  $r(x,y)$ ). To keep it simple, we assume  $r$  and  $(p_e, q_e)$  are known and fixed constants. But we still have many  $p$ 's and  $q$ 's which will satisfy  $L - LR=0$ , in fact two unknowns for every equation. This makes clear that shape from shading is under-constrained or "ill-posed" mathematical problem.

Just in case you are thinking that we might be able to use regions of constant intensity, note that lines of constant luminance in the image (called isophotes) do not necessarily imply constant  $(p,q)$ :

A solution to ambiguity (that we'll explore in detail later in optic flow motion field estimation) is to impose 1) a region-based smoothness constraint (a local constraint) and 2) boundary conditions (global constraint). Smoothness constraints can be formulated as "Bayesian priors", but more on this later. Let's see how Ikeuchi and Horn got around the problem of ill-posedness.

### Implementing a smoothness constraint.

The intuition is that many objects tend to be smooth. What does this mean in terms of how surface normals change across a surface? We would expect smooth surfaces to have small spatial derivatives. If we made a guess as to what the surface normals were, we could measure the degree of smoothness using first or second derivative magnitudes, and if too big, try to change the shape to make the surface smoother. The idea is to write an algorithm that searches for a surface that satisfies  $L - LR=0$  AND has low spatial derivatives.

Let us follow the approach of Ikeuchi and Horn (1981), and enforce a surface smoothness assumption (or constraint) by requiring that the squared values of the Laplacians of  $p$  and  $q$  be small. The Laplacians are:

$$\nabla^2 p = \frac{\partial^2 p}{\partial x^2} + \frac{\partial^2 p}{\partial y^2}$$

$$\nabla^2 q = \frac{\partial^2 q}{\partial x^2} + \frac{\partial^2 q}{\partial y^2}$$

We then construct a local cost function function:

$$e(x, y) = (L(x, y) - L_R(p, q))^2 + \lambda((\nabla^2 p)^2 + (\nabla^2 q)^2)$$

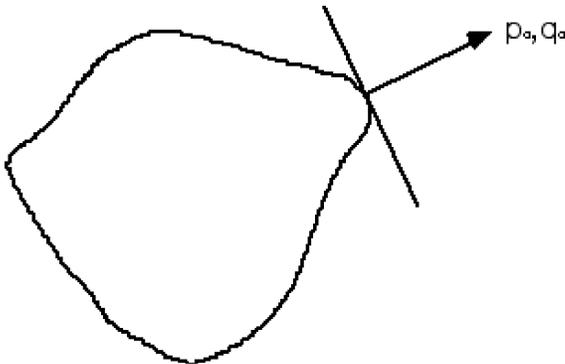

We want  $e(x,y)$  to be small. This will be the case if  $(p,q)$  is chosen so that the first term tends toward zero, and if the spatial derivatives are small (i.e. because we've chosen  $p,q$  to change slowly). But we want this local cost function to be small over the whole image.

So we construct a global cost "functional" by integrating over the whole image:

$$e[p(x, y), q(x, y)] = \iint (L(x, y) - L_R(p, q))^2 + \lambda((\nabla^2 p)^2 + (\nabla^2 q)^2) dx dy$$

The goal is to find  $(p,q)$  at each point  $(x,y)$  which makes the global error or cost,  $e[p,q]$  as small as small as possible.  $\lambda$  is a weighting function on the smoothness. For example, it should be big if we have reason to believe our data are noisy--i.e. we want to trust our prior smoothness constraint over the unreliable data.

The boundary values can also be used to constrain the solution, and may be necessary at times to produce a unique solution. They are also important to prevent smoothing over discontinuities. What are the boundary conditions?

The surface normal can be read directly off the image if the boundary contours are known. But we have a problem, at smooth occluding bounding contours,  $p_o$  and  $q_o$  (the spatial rates of change of the surface depth away from the view-point) are infinite. And if the bounding contours are not smooth, but sharp, the surface normal is not defined there.

One solution is to change coordinates to ones that don't blow up at boundaries. Stereographic coordinates are one solution to avoiding infinities at the boundaries (Ikeuchi and Horn, 1982).

$$f = \frac{2p \sqrt{1 + p^2 + q^2} - 1}{p^2 + q^2}$$

$$g = \frac{2q \sqrt{1 + p^2 + q^2} - 1}{p^2 + q^2}$$

Another representation that will avoid the boundary problem is slant and tilt introduced earlier (e.g, Mamassian and Kersten (1995)).

It can be shown that minimizing the above error function is equivalent to maximizing the posterior probability of the map of surface  $p(x)$ 's and  $q(x)$ 's conditional on  $L(x,y)$ . Using Bayes, the generative model determines the likelihood, and the laplacians of the gradient parameters determine the smoothness prior.

## Human perception of shape from shading

### Perception of shape from shading & lighting direction

Some studies seem to indicate that human observers are not very accurate at estimating the local orientation of surface normals. It has also been shown that human visual judgments show a bias towards the fronto-parallel plane.

We also seem to have difficulty in estimating the slant of a light source (Todd, J. T., & Mingolla, E., 1983; Mingolla, E., & Todd, J. T. 1986). We are better at the tilt.

One problem with our above shape from shading analysis is that we assumed light source direction is known.

Human observers do assume that the light source is from above. This can be seen in the age-old "crater illusion" in which we have vertical luminance gradients of intensity giving an impression of a convex object on the left, and a concavity on the right (Ramachandran, V. S., 1988). (See previous lecture and code below that makes a bump lit from above and one that is upside-down). However, the light from above prior is relatively weak, which can be seen when vision is given a richer shape structure (Morgenstern, Y., Murray, R. F., & Harris, L. R. (2011).

Interestingly, there also seems to be a slight bias towards assuming the light source is coming from the left (Sun & Perona, 1998).

### Shading and contour interaction

A challenging problem is understanding how shape-from-contour interacts with shape from shading. Contour can override shading information. Let's cut out sections of part of an apparent sphere:

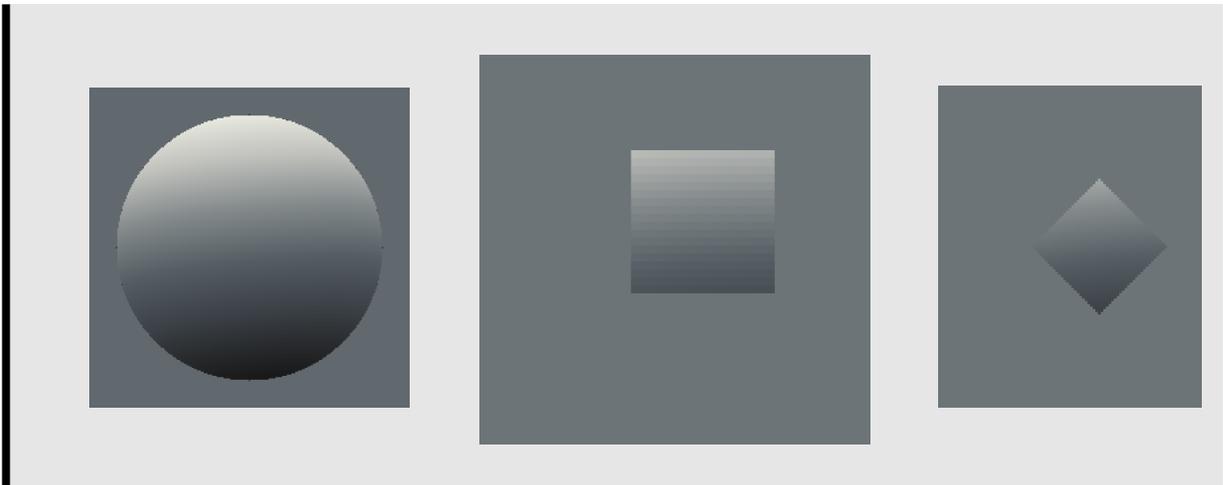

```
s={-10,100,10}; s=N[s/Sqrt[s.s]];
temp=Transpose[Table[normface[x,y].s,{x,-1.2,1.2,0.01},{y,-1.2,1.2,0.01}]];
b1=ArrayPlot[temp,Mesh->False,Frame->False,PlotRange->{-1,1}];
```

```
s={-10,100,10}; s=N[s/Sqrt[s.s]];
temp=Transpose[Table[If[(x<-1/4 || y<-1/4) || (x>3/5 || y>3/5),0,normface[x,y].s],{x,-1.2,1.2,0.01},{y,-1.2,1.2,0.01}]];
b2=ArrayPlot[temp,Mesh->False,Frame->False,PlotRange->{-1,1}];
```

```
s={-10,100,10}; s=N[s/Sqrt[s.s]];
temp=Transpose[Table[If[Abs[x]+Abs[y]>.5,0,normface[x,y].s],{x,-1.2,1.2,0.02},{y,
b3=ArrayPlot[temp,Mesh->False,Frame->False,PlotRange->{-1,1}];
```

The same patch taken from the image of the sphere can appear as an apparent cylinder, or diamond depending on the bounding contours:

```
GraphicsRow[{b1, b2, b3}]
```

How the visual system incorporates boundary conditions is still not well-understood. This could be done either through low-level "propagation" analogous to the Ikeuchi & Horn algorithm, or it could be done by using the contour to "index" shape classes (polyhedra, cylinders, spheres, pills, chiclets, etc..) with which to infer the interior shape.

### Demo idea

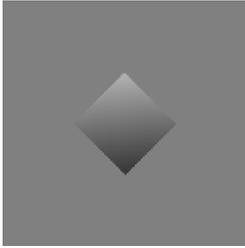

Another demo (due to David Knill) you can try to make yourself is generate a vertical sine-wave grating. Make the contours at the top and bottom have either 1) the same frequency as the grating or 2) twice the frequency.

One research problem is how do specularities affect the convex vs. concave perception in the above figures? It has been found that human observers can use the stereoscopic position of a specularity (which is in front of a concave surface, and behind a convex surface) to disambiguate the shape (Blake and Bülhoff, 1990; 1991).

### Project idea

Here is a project idea. One would expect that the influence of contour on shape-from-shading would depend on whether the contour is "attached" to the shaded region or not. A simple way of manipulating this is to use stereo. For example, one could make the boundary of a sphere to appear either at the correct boundary (i.e. towards the back of the bulge), or in front of the bulge, as if it is a hole. Perceived shape should be affected. One might even be able to design a shading pattern that looks very different depending on what the boundary gets attached to. For a discussion of "intrinsic" vs. "extrinsic" contours, see: Nakayama, K., & Shimojo, S. (1992).

Suppose that the diamond boundary below appeared as a diamond-shaped whole. Would one still interpret the shading as a pill, or would the shape of the internal region now appear more spherical?

## Psychophysics

There have been a number of studies of the kinds of psychophysical errors made in slant and tilt judgements with a shape-from-shading algorithm that assumes smoothness in slant and tilt and knows the boundary values (e.g. Mamassian and Kersten, 1995). Mamassian and Kersten investigated the perception of local surface orientation for a simple object with regions of elliptic (egg-shaped) and hyperbolic (saddle-shaped) points. The local surface orientation was measured by the slant and tilt of the tangent plane at different points of the surface under several different illumination conditions. They found an underestimation of the perceived slant, and a larger variance for the perceived tilt. They also found that subjects were better at estimating the surface orientation when the shape was locally egg-shaped rather than saddle-shaped or cylindrical. From converging evidence based on (i) the light direction most consistent with the observer's settings, (ii) a supplementary experiment where the object is displayed as a silhouette, and (iii) the computer simulations of the shape from shading algorithm, they concluded that the occluding contour was the dominant source of information used by the observers.

At this point, very little is known about the neurophysiology of shape from shading/contour, although there has been speculation about the role of V1 spatial filters (e.g. simple cells) in the local estimate of shape; see some early ideas by Lehky and Sejnowski (1988), and by Pentland (1982). Knill and Kersten showed that orthogonal oriented linear filters could be used to estimate surface normals for Lambertian surfaces; however, we have very little idea of how neural systems may represent parameters of shape. Even basic issues such as viewpoint dependent (via extrinsic geometry) vs. viewpoint dependent (via intrinsic geometry) representations are unclear.

## Neuroimaging

There have been a number of studies of the neural basis of human object and shape perception using fMRI. For example, see: Kourtzi and Kanwisher (2000) and Moore and Engel, (2001). See also Mamassian et al. (2003).

## Next time

### Bayes formulation of shape from shading & bas-relief

#### Task-dependency

##### ■ How to pick? Shape from X1 or X2 or X3

How should a visual system decide what kind of shape cue it has (shading from lambertian material, shading from shiny material, shading due to texture), and thus what kind of algorithm to use? One approach is to run a set of experts in parallel and pick the solution from the one that seems to "know what it is doing". Another approach is to use robust algorithms that are not sensitive to the details of the cues.

##### ■ How to integrate? Shape from X1 and X2 and X3

Later in the course, we will look at the problem of cue integration for depth and shape.

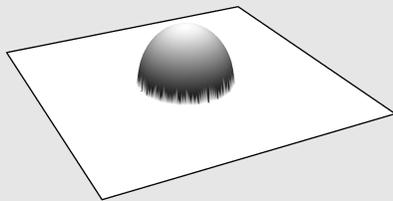

## Introduction to motion analysis

### Appendices

#### *Mathematica* demonstration of: Illumination direction & shape ambiguity using the lambertian model

##### ■ Lambertian hemisphere

```
bump[x_, y_] := If[x^2 + y^2 > 1, 0, Sqrt[1 - x^2 - y^2]];  
g1 = Plot3D[bump[x, y], {x, -3, 3}, {y, -3, 3}, PlotPoints → 64,  
  PlotRange → {0, 2}, Mesh → False,  
  Lighting → {"Directional", RGBColor[1, 1, 1], {{5, 5, 4}, {5, 5, 0}}},  
  ViewPoint → {1, 2, 1}, AxesLabel → {"x", "y", "z"}, Ticks → False,  
  AspectRatio → 1, ImageSize → Small, Boxed → False, Axes → False]
```

### ■ Calculate surface normals of surface

```
Clear[nx, ny]; little = 0.001; big = 1000;

nx[x_, y_] := Evaluate[D[bump[x, y], x]];
ny[x_, y_] := Evaluate[D[bump[x, y], y]];
nx[x_, y_] := big /; x^2 + y^2 == 1
ny[x_, y_] := big /; x^2 + y^2 == 1
nx[x_, y_] := 0. /; {x^2 + y^2 > 1}
ny[x_, y_] := 0. /; x^2 + y^2 > 1
```

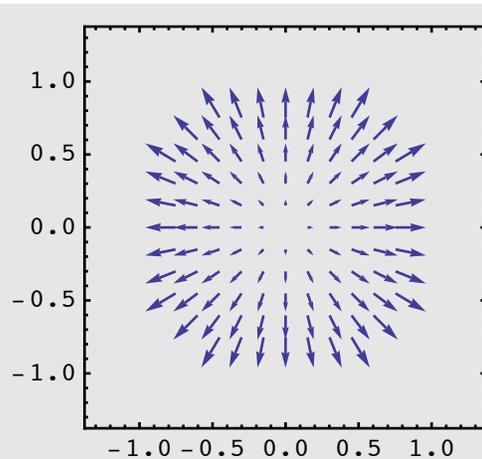

$nx[x,y]$  is  $\frac{\partial z}{\partial x}$ , and similarly for  $ny$ . The rate of change of depth range is greatest as the face slopes away from the viewpoint:

### ■ Lambertian rendering: specification for normals, light, reflectance

#### ■ Unit surface normals

Normalize the surface normal vectors to unit length:

```
normface[x_, y_] := -{nx[x, y], ny[x, y], 1} /
  (Sqrt[nx[x, y]^2 + ny[x, y]^2 + 1]);
VectorPlot[{normface[x, y][[1]], normface[x, y][[2]]}, {x, -1.2, 1.2},
  {y, -1.2, 1.2}, ImageSize -> Small]
```

#### ■ Render bump surface

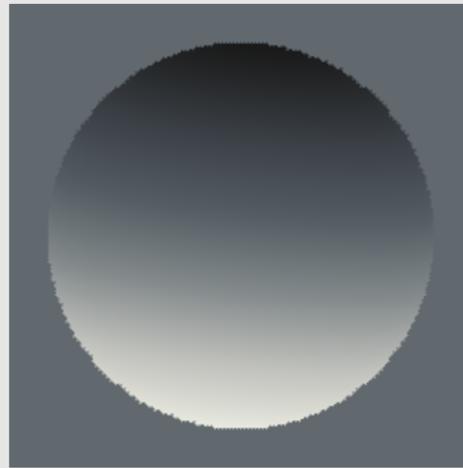

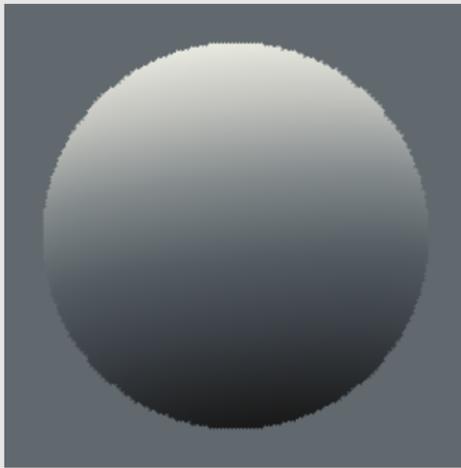

Use the lambertian equation to render the surface illuminated from above and from below.

```

a[x_, y_] := 1;
s = {-10, 100, 10}; s = N[s / Sqrt[s.s]];
b1 = DensityPlot[a[x, y] * normface[x, y].s, {x, -1.2, 1.2},
  {y, -1.2, 1.2}, Mesh → False, PlotPoints → 64, Frame → False,
  PlotRange → {-1, 1}, ColorFunction → "GrayTones"];

## Linear approximation

### ■ Linear approximation to the Lambertian generative model for shading

The image formation constraint that we have used is non-linear. It is worth asking to what degree a linear approximation would be adequate-- a question which has been addressed by Knill and Kersten (1990) and by Pentland (1990). If a linear approximation works, then the inverse problem is linear.

Let's derive a linear approximation to:

$$L_R(p, q) = \frac{r(pp_e + qq_e + 1)}{\sqrt{(p^2 + q^2 + 1)(p_e^2 + q_e^2 + 1)}}$$

```

Lmodel[pn_,qn_,pe_,qe_] := ({pn,qn,-1}/Sqrt[pn^2+qn^2 + 1]).({pe,qe,-1}/Sqrt[pe^2+

```

where we use the notation  $p \rightarrow pn$ ,  $q \rightarrow qn$ .

### Taylor's series

We can expand the image luminance in a Taylor series about  $\{pn, qn\} = \{0, 0\}$ . Recall that this is done by calculating successive derivatives at  $\{pn, qn\} = \{0, 0\}$ , and then substituting  $\{pn, qn\} \rightarrow \{0, 0\}$ . The first derivative with respect to  $pn$  is:

```
D[Lmodel[pn, qn, pe, qe], pn] /. {pn -> 0, qn -> 0}
```

$$\frac{1}{\sqrt{3}}$$

Note that this is the cosine of the slant of the light source (see previous lecture).

*Mathematica's Series[]* function puts the Taylor series together for us. Here is the expansion up to linear terms:

```
Series[Lmodel[pn, qn, pe, qe], {pn, 0, 1}, {qn, 0, 1}]
```

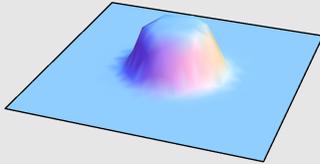

$$\left( \frac{1}{\sqrt{3}} + \frac{qn}{\sqrt{3}} + O[qn]^2 \right) + \left( \frac{1}{\sqrt{3}} + O[qn]^2 \right) pn + O[pn]^2$$

You can improve the approximation by including quadratic terms: `Series[Lmodel[pn, qn, pe, qe], {pn, 0, 2}, {qn, 0, 2}]`.

Try it out on `bump[x_, y_] := (1/4) (1 - 1/(1 + Exp[-10 (Sqrt[x^2 + y^2] - 1)]))`;

```
Clear[bump, x, y];
bump[x_, y_] := (1/4) (1 - 1/(1 + Exp[-10 (Sqrt[x^2 + y^2] - 1)]));
pn[x_, y_] := Evaluate[D[bump[x, y], y]];
qn[x_, y_] := Evaluate[D[bump[x, y], x]];
```

```
Plot3D[bump[x, y], {x, -3, 3}, {y, -3, 3}, Mesh -> False,
PlotRange -> {0, .5}, ImageSize -> Small, Axes -> False, Boxed -> False]
```

Light source:

```
{pe, qe} = {1, 1};
```

$$\text{Lapprox}[x_, y_] := \frac{1}{\sqrt{1 + pe^2 + qe^2}} + \frac{qe * qn[x, y]}{\sqrt{1 + pe^2 + qe^2}} + \frac{pe * pn[x, y]}{\sqrt{1 + pe^2 + qe^2}};$$

```
Lapprxom[x_, y_] := (1 + qe * qn[x, y] + pe * pn[x, y]) / Sqrt[1 + pe^2 + qe^2];
```

```
DensityPlot[Lappproxom[x, y], {x, -3, 3}, {y, -3, 3}, Mesh → False,
Frame → False, PlotPoints → 64, PlotRange → {0, 1},
ColorFunction → "GrayTones", ImageSize → Small]
```

**How could you use the above linear generative model for "shading from shape" to devise a solution to the inverse problem of "shape from shading"?**

In the next lecture, we'll look at a simple algorithm for shape from shading that assumes the linear generative model.

■ **Is shape from shading really ill-posed? Formal (exact) solution to the classic problem: lambertian, point light source**

Given a Lambertian reflectance, and a point light from the camera, the shape from shading problem is well-posed and a solution can be found (Dupuis and Oliensis, 1994).

■ **Shape from shading on a "cloudy day"--diffuse lighting**

Most theoretical work on shape from shading started assuming point light sources, but diffuse lighting is the more realistic case. The generative physical problem becomes complicated. Ray-tracing and radiosity methods provide forward generative models (eg. Greenberg, 1989; Foley et al., 1990). But the straightforward inverse problem is impractical--can't check out all the ray-tracing bounces!

For an elegant solution to the problem of shape-from-shading on a cloudy day, see: Langer, M. S. & Zucker, S. W. (1994)
